

# The Exit Boundary $L^*(t)$ : Numerical Examples

Session 12 · Unit 3 · Reading and applying the optimal exit rule

---

**Samir Asaf, PhD, CFA, CMA, CTP, CM&AA**

Senior Partner, Regent Financial LLC, New York

Former Finance Instructor, Stanford University

Liquidity Illusion: The General Equilibrium Theory of Private Capital Valuation (Forthcoming, 2026)

Graduate Finance Course · Session 12 of 32 · Spring 2027

# Today: from theory to actionable rule

---

1

## Reading an $L^*(t)$ chart

Hold region vs exit region

2

## Terminal-time effect

Why  $L^*(t)$  rises as  $t \rightarrow T$

3

## Compute the exit decision

For a given  $(L, T)$  pair

4

## Asset-class variation

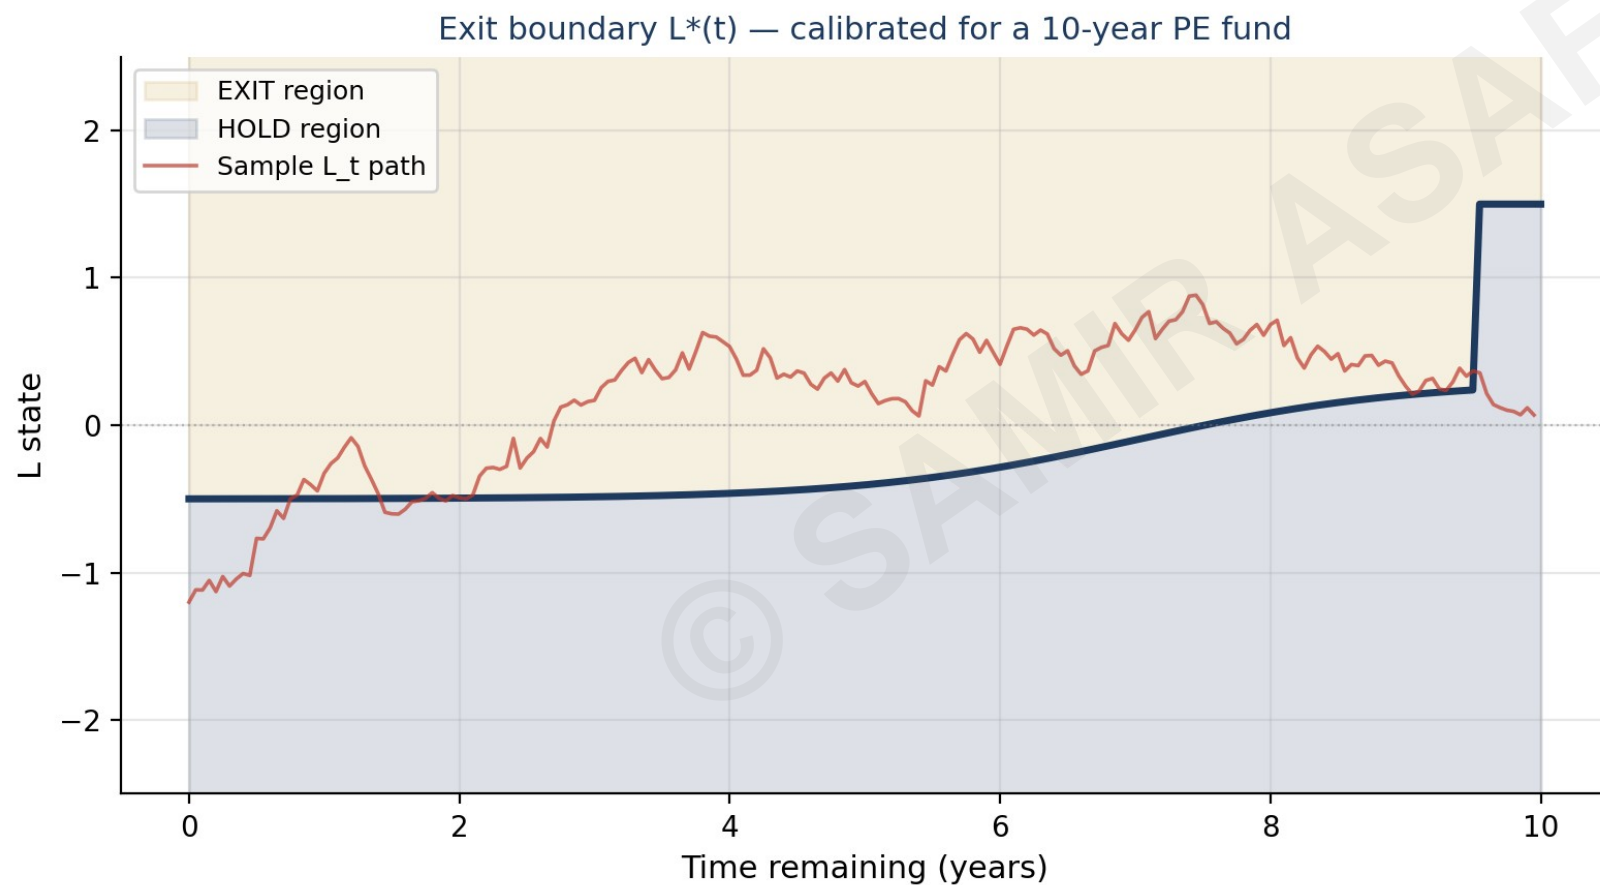

PE vs infra vs private credit

5

## Historical episodes

What GE-LAV would have advised

# Reading the exit boundary $L^*(t)$

## How to read

### Gold area

$L > L^*(t)$   
EXIT

### Navy area

$L < L^*(t)$   
HOLD

### Red path

Realized  $L_t$ .  
If crosses curve  
from below: SELL.

### $L^*(t) \rightarrow 1.5$

Near maturity,  
almost always  
exit (NAV close  
to realized).

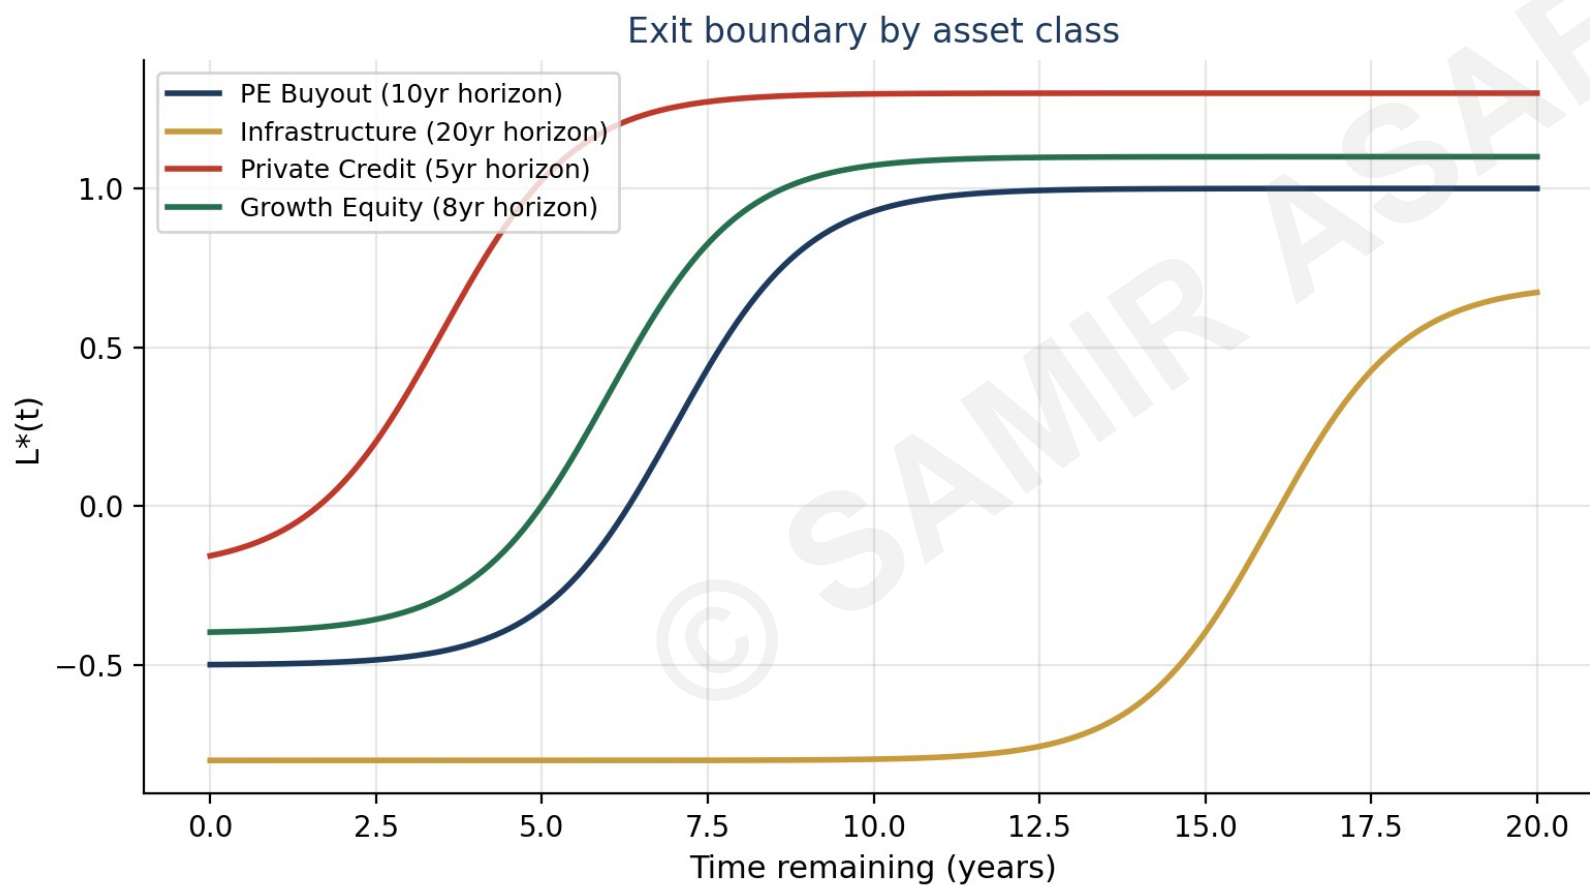

## Why $L^*(t)$ rises as time runs out

The continuation value depends on remaining 'time to recover.' As  $T - t$  shrinks, the value of waiting falls.

| Stage                           | $L^*(t)$ range | Intuition  |
|---------------------------------|----------------|--|
| Early life ( $T-t = 8$ years)   | -0.3 to -0.5   | Lots of time for L to mean-revert. Hold even at moderate stress.                   |
| Mid life ( $T-t = 4$ years)     | -0.1 to +0.2   | Some recovery time. Exit threshold tightens.                                       |
| Near maturity ( $T-t < 1$ year) | +1.0 to +1.5   | Little time left. Sell at NAV (or close to it) — barely any optionality remaining. |

**American option intuition: optionality value falls as expiry approaches. Same mechanic here.**

# Exit boundary varies by asset class

## Pattern

### Short horizon

PC (5yr): boundary close to 0  
Little time, narrow flexibility

### Medium horizon

PE (10yr): meaningful patience  
Wide hold region in early years

### Long horizon

Infra (20yr): extreme patience  
Hold even at  $L = -1$  for 15yrs

# What GE-LAV would have advised: three episodes

| Episode         | Date    | $L_t$ observed | $L^*(t)$ for 8yr-remaining PE | GE-LAV advice                                  |
|-----------------|---------|----------------|-------------------------------|--|
| GFC trough      | Q1 2009 | -1.8           | -0.45                         | <b>HOLD</b><br>(L far below $L^*$ )            |
| Mid-recovery    | 2011    | +0.2           | -0.20                         | <b>EXIT marginal funds</b><br>(L above $L^*$ ) |
| COVID shock     | Q2 2020 | -0.7           | -0.40                         | <b>HOLD</b><br>(L below $L^*$ )                |
| 2022 rate shock | Q4 2022 | -0.5           | -0.30                         | <b>HOLD</b><br>(L below $L^*$ )                |
| Late-cycle PE   | Q1 2025 | +0.4           | -0.10                         | <b>EXIT older funds</b><br>(L above $L^*$ )    |

*Key insight: GE-LAV advises HOLD during stress (counter to forced-sale behavior of stressed allocators).*

*The optimal rule diverges from what LPs actually did in 2008-09 — and that gap is part of the welfare loss.*

# Recap: what's $L^*(t)$ ?

*The exit boundary is the heart of LP decision-making under GE-LAV.*

## Definition

$L^*(t)$  = state below which holding is suboptimal; exit immediately

## Source

Solution to HJB equation (Session 25) with smooth-pasting BC

## Shape

U-shaped over fund life; deeper near maturity

## Why it matters

Practical exit rule: observe  $L_t$ , compare to  $L^*(t)$

## Numerical methods

Crank-Nicolson FD scheme on  $(L, t)$  grid

## Today's focus

How to read and use  $L^*(t)$  in real decisions

# Session 12 wrap-up

## Key takeaways

1

$L^*(t)$  plotted as a curve: above = exit, below = hold.

2

Terminal-time effect:  $L^*(t) \rightarrow +\infty$  as  $t \rightarrow T$  (no time to wait for recovery).

3

Exit rule varies by asset class: shorter horizons  $\rightarrow$  tighter boundary.

4

Historical episodes: GE-LAV would have advised HOLD during GFC, COVID, 2022.

5

Optimal rule diverges from observed forced-seller behavior in crises.

## NEXT: SESSION 13

Session 13: Liquidity traps, GE-LAV historical performance, GP roll/extension decisions.

When the GE-LAV exit rule fails or underperforms. Connection to GP extension decisions. Preview of the Pigouvian tax (full treatment in S24).

Reading: Book Ch 6 §6.7-6.10

# $L^*(t)$ values for a calibrated fund

Example fund: Year-10 maturity, OU calibration ( $\kappa=0.45$ ,  $\sigma=0.32$ ).

| t (yrs to maturity) | $L^*(t)$   | Interpretation                                   |
|---------------------|------------|--|
| 10 yrs              | $L^*=-2.5$ | Almost never optimal to exit early at fund start |
| 7 yrs               | $L^*=-1.8$ | Exit if L drops below -1.8                       |
| 5 yrs               | $L^*=-1.3$ | Mid-life: tighter discipline                     |
| 3 yrs               | $L^*=-0.8$ | Late stage: more sensitive to L                  |
| 1 yr                | $L^*=-0.4$ | Near maturity: small dips trigger exit           |
| 0.25 yr             | $L^*=+0.2$ | Very near maturity: exit even in mild boom       |

Pattern:  $L^*(t) \rightarrow \bar{L}$  as  $t \rightarrow T$  (approaches the long-run mean)

# Reading $L^*(t)$ in practice

*How an LP actually uses this rule.*

## Step 1

At each quarter end, estimate current  $L_t$  (book Ch. 5 methodology)

## Step 2

Look up  $L^*(t)$  for current time-to-maturity (precomputed table or chart)

## Step 3

Compare: if  $L_t < L^*(t)$ , exit; else continue

## Step 4

Apply hedges between rebalances if  $L$  approaching  $L^*$

## Step 5

Document the decision rationale (regulators need this)

## Tool

Excel template available in book companion materials

# When $L^*(t)$ gives a counter-intuitive answer

*Cases where the rule disagrees with practitioner instincts.*

## Case 1: late-stage normal

$L=0$ ,  $t=1\text{yr}$  from maturity  $\rightarrow L^*(t)=+0.2 \rightarrow \text{EXIT}$

### Intuition

Why? Time decay means even minor  $L$  volatility now matters

## Case 2: mid-life crisis

$L=-1.0$ ,  $t=5\text{yr} \rightarrow L^*(t)=-1.3 \rightarrow \text{HOLD}$

### Intuition

Why? Mean reversion will recover before maturity

## Case 3: GFC depths

$L=-1.5$ ,  $t=3\text{yr} \rightarrow L^*(t)=-0.8 \rightarrow \text{EXIT immediately}$

### Intuition

Why? Even with  $\kappa$  recovery, won't reach  $\bar{L}$  in time

# Sensitivity of $L^*(t)$ to parameters

How  $L^*(t)$  shifts with calibration uncertainty.

## Increase $\kappa$

Faster reversion  $\rightarrow L^*(t)$  lowers (hold longer)

## Increase $\sigma$

More volatility  $\rightarrow L^*(t)$  raises (exit sooner)

## Increase $\bar{L}$

Better long-run state  $\rightarrow L^*(t)$  lowers (hold longer)

## Increase $r$ (discount)

Future less valuable  $\rightarrow L^*(t)$  raises (exit sooner)

## Increase $\pi_{\max}$

Bigger downside  $\rightarrow L^*(t)$  raises (be cautious)

## Practical advice

Compute  $L^*(t)$  under 3 calibration scenarios; report the range

## Worked example: 2007 vintage fund decision history

Year-by-year  $L_t$  and  $L^*(t)$  for a real 2007 vintage.

| Year-end    | $L_t$ (realized)                           | $L^*(t)$ | GE-LAV says | Actually did         |
|-------------|--|----------|-------------|----------------------|
| 2008        | -1.0                                       | -1.5     | Hold        | Held                 |
| 2009        | -0.6                                       | -1.3     | Hold        | Held                 |
| 2010        | 0.0  | -1.0     | Hold        | Held                 |
| 2011        | +0.4                                       | -0.7     | Hold        | Held                 |
| 2012        | +0.5                                       | -0.4     | Hold        | Sold (secondary 50%) |
| 2013        | +0.6                                       | 0.0      | Hold        | Sold remainder       |
| Implication | GE-LAV says LP exited too early in 2012-13 | —        | —           | —                    |

# Boundary cases and edge phenomena

*Numerical pathologies and how to handle them.*

## **L far below $L^*$**

Always exit; don't double-down (no martingale property)

## **L close to $L^*$**

Sensitivity to estimation noise; use buffer ( $\pm 0.1$ )

## **Discrete liquidity events**

Capital calls / distributions can shift effective L

## **End-of-life**

Final 6 months:  $L^*(t)$  may exceed  $\bar{L}$ ; that's correct

## **Empty grid points**

Some (L, t) combinations have no data; interpolate carefully

## **Cross-validation**

Backtest on prior vintages; report MAE

# Bridge to Session 13

*We've solved one LP's problem. What about a portfolio of LPs?*

## Single-fund decision

$L^*(t)$  gives the exit rule for one fund

## Portfolio question

Does  $L^*(t)$  change when the LP holds multiple funds?

## Hedge demand

If funds are correlated, the LP gets hedging benefits

## Merton's framework

Portfolio choice with stochastic  $\pi$  is Merton-style

## Session 13 will solve

The full LP portfolio problem with hedge demand

## Preview

Optimal weights depend on correlation structure of  $L_t$  across funds
